INDIAN PREMIER LEAGUE PLAYER DATA ANALYSIS USING PYTHON AND R

INTRODUCTION

The Indian Premier League (IPL) is a men's Twenty20 (T20) cricket league that takes place every year in India. For sponsorship purposes, it is also known as the TATA IPL. Ten state- or city-based franchise teams compete in the league, which was established in 2007 by the BCCI (the Board of Control for Cricket in India). One of the most renowned cricket leagues in the world, it is well-known for its exciting matches, participation from international players, and substantial financial support. Since its inaugural season, the IPL has advanced significantly.

OBJECTIVES

- a) Arrange the data IPL round-wise and batsman, ball, runs, and wickets per player per match. Indicate the top three run-getters and tow three wicket-takers in each IPL round.
- b) Fit the most appropriate distribution for runs scored and wickets taken by the top three batsmen and bowlers in the lost three IPL tournaments. Rename the districts as well as the sector, viz. rural and urban.
- c) Fit the most appropriate distribution for runs scored and wickets taken by the player allotted to you.
- d) Last three-year performance with latest salary 2024
- e) Significant Difference Between the Salaries of the Top 10 Batsmen and Top Wicket-Taking Bowlers Over the Last Three Years

BUSINESS SIGNIFICANCE

Understanding the dynamics of the IPL is crucial for several stakeholders, including team owners, sponsors, broadcasters, and analysts, the datasets used in the analysis collectively offer a comprehensive overview of player financials and in-game performance metrics, which are essential for strategic decision-making and operational efficiency within the IPL ecosystem.

• Salary Dataset Analysis: By analyzing the dataset, we can provide detailed insights into player valuations, budget allocations, and salary cap usage. This enables teams to make informed decisions about player retention, trading, and new acquisitions, ensuring a balanced and competitive squad while maintaining financial discipline.

- **Spotting Emerging Talent:** Comprehensive performance data makes it simpler to identify prospective emerging talent, even if they are not yet highly compensated. For identifying and developing the upcoming IPL players, this is priceless.
- Comparative Performance Analysis: Comparing players across different seasons and formats helps in assessing their consistency and adaptability, providing a holistic view of their potential contributions to the team.

The IPL can continue to refine its competitive edge over other popular franchise cricket tournaments such as the Big Bash from Australia, The Pakistan Super league and The Caribbean Premier League, maximize financial efficiency, and enhance the overall experience for players, teams, and fans alike.

RESULTS AND INTERPRETATION IN R CODE

A) Using IPL data, establish the relationship between the player's performance and payment he receives and discuss your findings. Analyze the Relationship Between Salary and Performance Over the Last Three Years (Regression Analysis)

Regression Analysis Results

1. Runs Scored vs. Salary

Regression Model Summary:

Result:

```
Call:
```

 $lm(formula = y \sim X)$

Residuals:

```
Min 1Q Median 3Q Max
-990.8 -341.8 -68.2 278.5 1428.5
```

Coefficients:

```
Estimate Std. Error t value Pr(>|t|)
(Intercept) 360.666 34.160 10.56 < 2e-16 ***
X 1.087 0.136 7.99 2.75e-14 ***
```

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' '1

Residual standard error: 440 on 307 degrees of freedom

Multiple R-squared: 0.1721, Adjusted R-squared: 0.1694

F-statistic: 63.84 on 1 and 307 DF, p-value: 2.752e-14

Interpretation: Runs Scored vs. Salary:

- There is a statistically significant relationship between runs scored and salary, with players earning more as they score more runs.
- However, the R-squared value is relatively low (0.1721), suggesting that other factors besides runs scored also significantly influence player salaries.

2.) Wickets Taken vs. Salary

Regression Model Summary:

Result:

Call:

lm(formula = y_wickets ~ X_wickets)

Residuals:

Min 1Q Median 3Q Max -641.62 -338.97 -26.62 308.80 865.60

Coefficients:

Estimate Std. Error t value Pr(>|t|) (Intercept) 89.94 370.62 0.243 0.811 X_wickets 27.22 20.16 1.350 0.192

Residual standard error: 428.2 on 20 degrees of freedom

Multiple R-squared: 0.08356, Adjusted R-squared: 0.03774

F-statistic: 1.824 on 1 and 20 DF, p-value: 0.192

Interpretation:

- here is no statistically significant relationship between wickets taken and salary for players with more than 10 wickets in 2022.
 - The low R-squared value (0.08356) and high p-value (0.192) indicate that wickets taken do not strongly influence salaries. Other factors might play a more critical role in determining the salaries of bowlers.

B) Perform Multiple regression analysis, carry out the regression diagnostics, and explain your findings. Correct them and revisit your results and explain the significant differences you observe.

```

Interpretation of Multiple Regression Analysis

The multiple regression analysis on the NSSO data, focusing on the state 'ORI', reveals that the MPCE_MRP (Monthly Per Capita Expenditure on Modified Reference Period) and Education are significant predictors of foodtotal q (total food expenditure). The initial model included other

variables (MPCE_URP, Age, Meals_At_Home, Possess_ration_card), but they were found to be statistically insignificant and were removed in the revised model. The final model explains approximately 45.8% of the variance in food expenditure (R^2 = 0.458). The coefficient for MPCE_MRP (0.3743, p < 0.0001) suggests that for every unit increase in MPCE_MRP, the food expenditure increases by 0.3743 units. Similarly, the coefficient for Education (0.8133, p < 0.0001) indicates a positive relationship, where higher education levels are associated with higher food expenditure. The VIF values in the revised model are well below the threshold of 10, indicating no multicollinearity issues. Despite the non-normality of residuals, the model provides a robust understanding of the key factors influencing food expenditure in the selected state.

Notes:

- [1] Standard Errors assume that the covariance matrix of the errors is correctly specified.
- [2] The condition number is large, 1.9e+04. This might indicate that there are strong multicollinearity or other numerical problems.

Interpretation of Multiple Regression Results

The multiple regression analysis of food expenditure in ORI reveals several significant predictors: MPCE_MRP, MPCE_URP, Age, Meals_At_Home, Possess_ration_card, and Education. Higher expenditures on MPCE_MRP and MPCE_URP, older age, more meals at home, and higher education levels are associated with increased food expenditure, while possessing a ration card corresponds to lower expenditure. The model is statistically significant, explaining 23.3% of the variance in food expenditure. However, diagnostic tests indicate potential issues with multicollinearity and non-normality of residuals, suggesting caution in interpreting the results.

B.) Using IPL data, establish the relationship between the player's performance and payment he receives and discuss your findings. Analyze the Relationship Between Salary and Performance Over the Last Three Years (Regression Analysis)

OLS Regression Results

Dep. Variable: Model: Method: Date: Time: No. Observations: Df Residuals: Df Model:	Least So Sun, 23 Jur 22:		Adj. F–st Prob		ic):	0.087 0.067 4.370 0.0421 -358.66 721.3 725.1

Omnibus: Prob(Omnibus): Skew: Kurtosis:		1.136 4.109	Jarq Prob	in-Watson: ue-Bera (JB) (JB): . No.);	2.109 12.788 0.00167 16.0	

Notes:

[1] Standard Errors assume that the covariance matrix of the errors is correctly specified.

Interpretation

The regression analysis reveals a statistically significant but weak relationship between a player's performance, measured by wicket_confirmation, and their salary in the IPL. The model shows that better performance slightly increases salary, with a coefficient of 17.75, but performance explains only 8.7% of the variance in salary, indicating other factors also heavily influence pay. While the model is significant (p = 0.0421), diagnostic tests suggest potential issues with the normality of residuals, implying that the model may not fully capture all relevant variables affecting salary.
